The catalytic performance of MoS<sub>2</sub> on the reduction of H<sub>2</sub>O<sub>2</sub> as well as methanol electrooxidation was investigated. The electrocatalyst was deposited onto the FTO/PET substrates by a simple spin-coating method. The results showed that the MoS<sub>2</sub> catalytic activity was largely improved in comparison to the FTO/PET substrate alone. In the process of methanol oxidation, MoS<sub>2</sub> exhibited a small overpotential and high current density compared to FTO/PET. In the electrocatalytic hydrogen evolution reaction (HER), the MoS<sub>2</sub> electrode demonstrated excellent catalytic properties, giving a low overpotential of only 79 mV at a large current density of 10 mA cm<sup>-2</sup>. The catalytic activity was correlated with the surface morphology of the MoS<sub>2</sub> film, which showed that the small MoS<sub>2</sub> grains with an average size of  $\approx 100$  nm are distributed uniformly throughout the MoS<sub>2</sub> film. This study suggests that the ultrathin MoS<sub>2</sub> films may be used as efficient electrocatalysts in the future for hydrogen evolution reaction and oxygen reduction reaction. It is known to weld together metal parts by means of resistance heating or laser radiation. The parts are heated together as a result of welding current being supplied to the parts. If one part is of metal and the other part is of a non-conductive material, then the part of the non-conductive material is heated to a greater extent than the other part, for example, by means of the radiation 2d92ce491b
